# Investigating the Relationship Between Food Contamination and Enteric Pathogen Infections in Infants Living in Low-to-middle-income Countries

**Monica Colon Vargas - University of Puerto Rico at Mayaguez**

**Andrew Peterson - Wheaton College**

**Victoria Penalver - University of Hawaii - West Oahu**

**Mentors: Dr. Daniel Sewell and Dr. Kelly Baker**

# What is an Enteric Infection?

- **Causes:** Bacteria, viruses, parasites and fungi
- **Transmission:** Eating/drinking contaminated food/water and fecal transmission
- **Symptoms of infection:** Abdominal pain, nausea/vomiting, diarrhea, reduced appetite, among others
- **Ex:** Bacterium E.coli

<https://health.mil/Military-Health-Topics/Combat-Support/Armed-Forces-Health-Surveillance-Branch/Global-Emerging-Infections-Surveillance-and-Response/Enteric-Infections>

# Why is this important?

- Dozens of pathogens are transmitted by fecal contamination in low-to-middle income countries causing:
  - 2.5 billion episodes of diarrhea
  - 580,000 deaths of children under five years per year
  - 40% of global health impact of foodborne illness

# Research Questions

---

**Question 1:** How are infants in low-to-middle income areas colonized with pathogens?

**Question 2:** Can milk contamination predict colonization?

# Safe Start and Market 2 Mouth Studies

---

## Q1 Data: Safe Start Study

- Evaluates impact of a caregiver food hygiene behavior change intervention at preventing enteric infection in infants
- Endline data - PCR data from stool samples collected after 9 months

## Q2 Data: Market 2 Mouth Study (M2M)

- Evaluates the impact of Safe Start intervention at preventing transmission of pathogens from dairy to infant food
- Midline data - Culture data from food samples after 8 months

# Data

---

- Based off of these two recent studies in Kenya on infant food and infections, we studied relationships between food and infections.
- Sample population: Infants at 8-9 months of age in Kenya.
- Only caregivers who fed their infants milk or food made with milk, (milk tea, milk porridge, etc.) are included in the M2M study.
- Some pathogens carry multiple pathogenic genes at once
  - EPECbfpA vs EPECeae

---

# How are infants colonized?

Analysis done using endline infant stool PCR samples

# Prevalence of Endline Data

# Prevalence of Endline Data

# Prevalence of Endline Data

# Prevalence of Endline Data

# Diversity of Endline Data

# Principal Component Analysis

- If we are to plot all 21 pathogens, we would need 21 dimensions
  - PCA reduces this to 2 dimensions/loadings
- K-means assigns each pathogen to a cluster

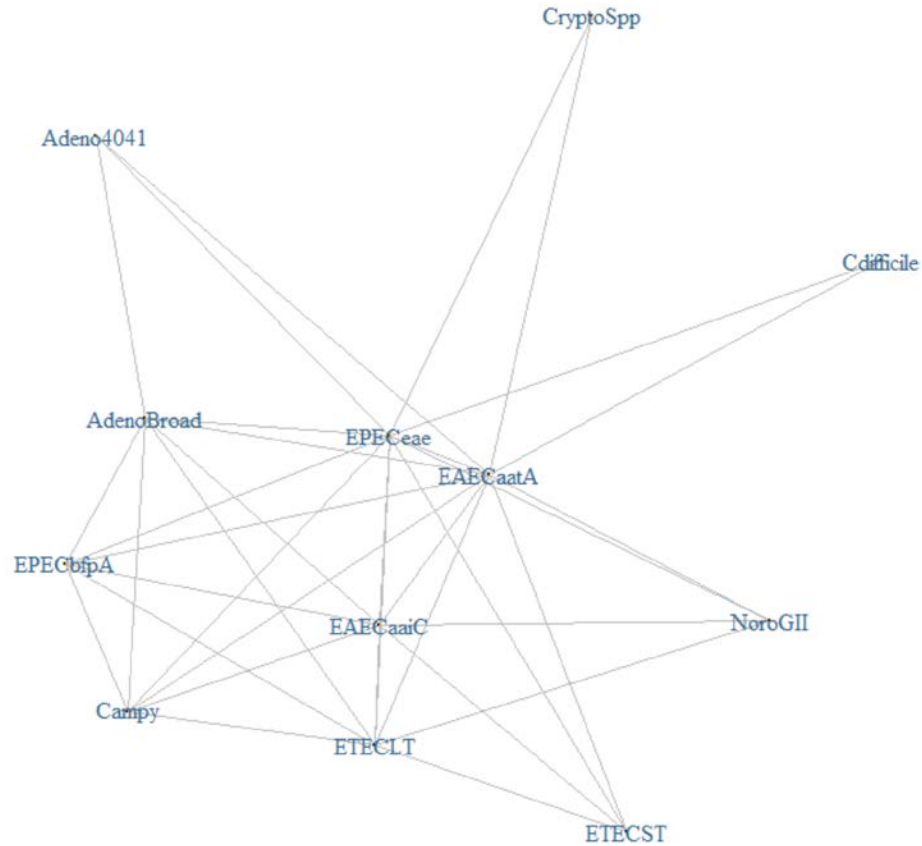

# Weighted Adjacency Matrix

# Weighted Adjacency Matrix

# Network

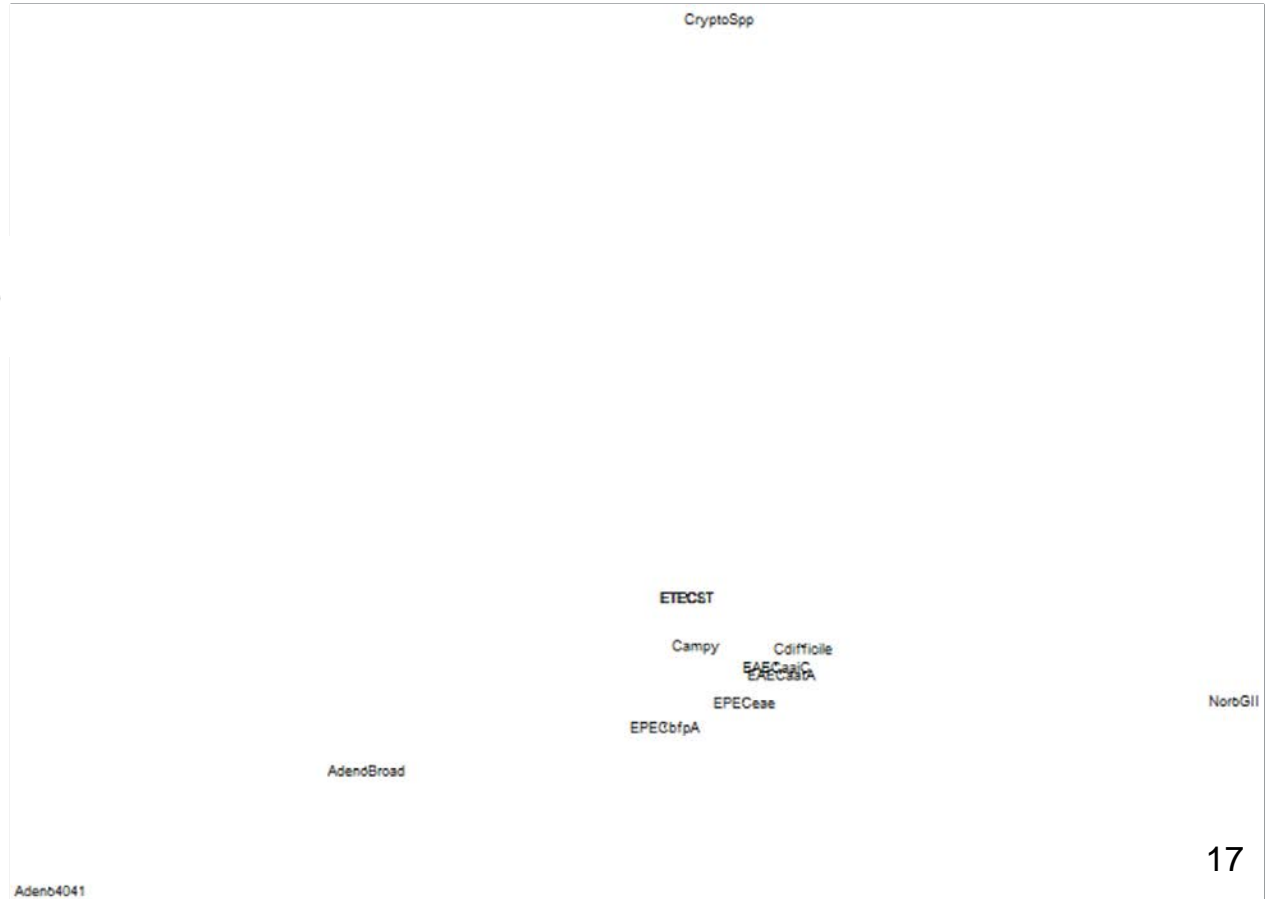

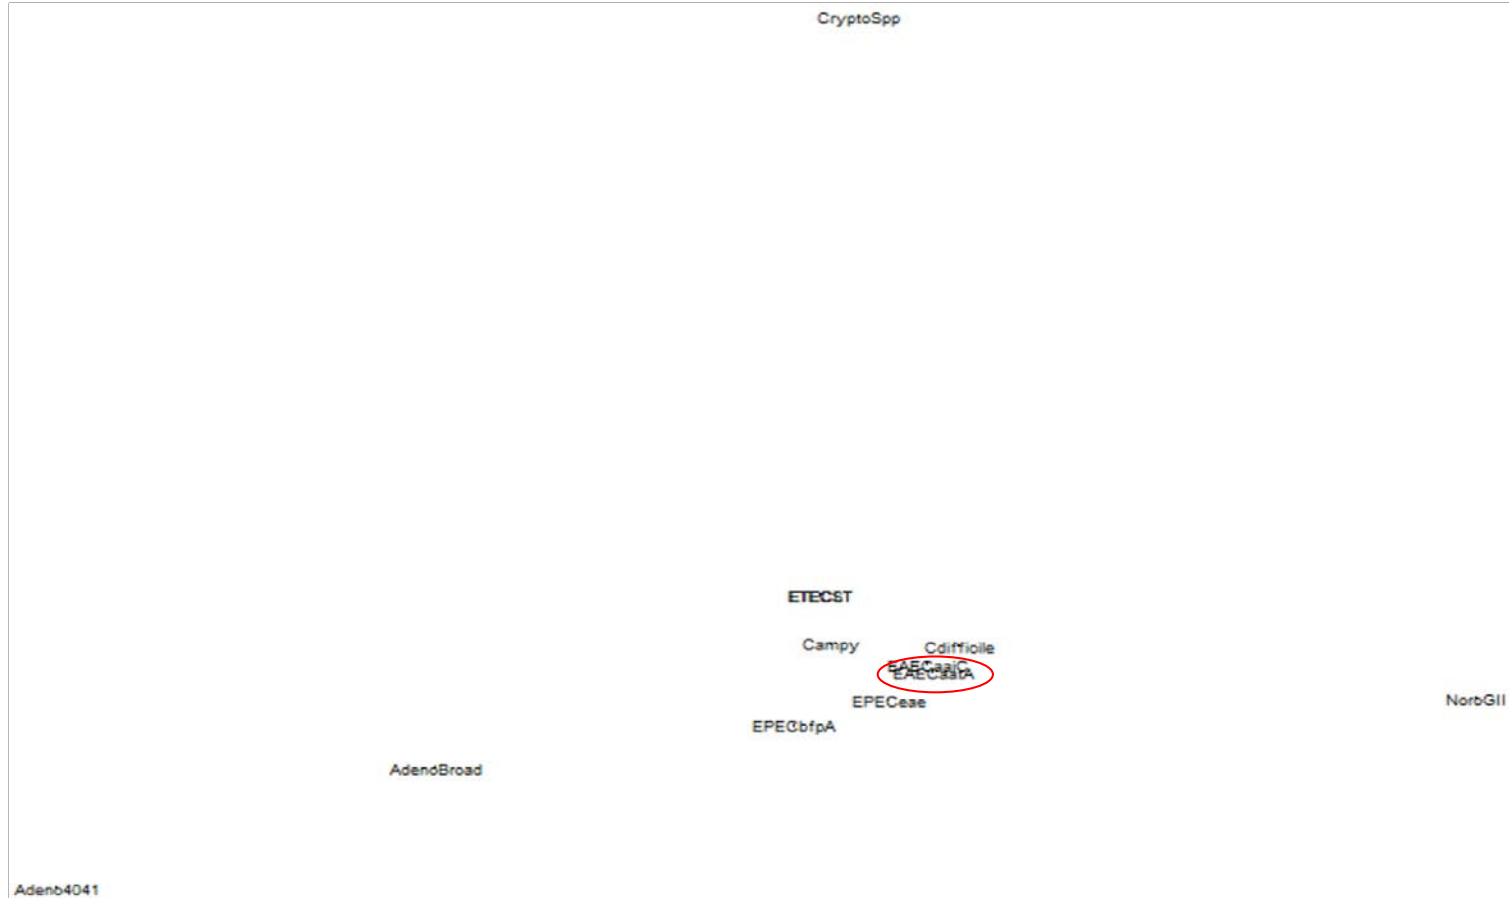

# Latent Space Model

$$\text{logit}(\text{Prob}(i \text{ and } j \text{ co-occur})) = \text{Intercept} + s_i + s_j - d(Z_i, Z_j)$$

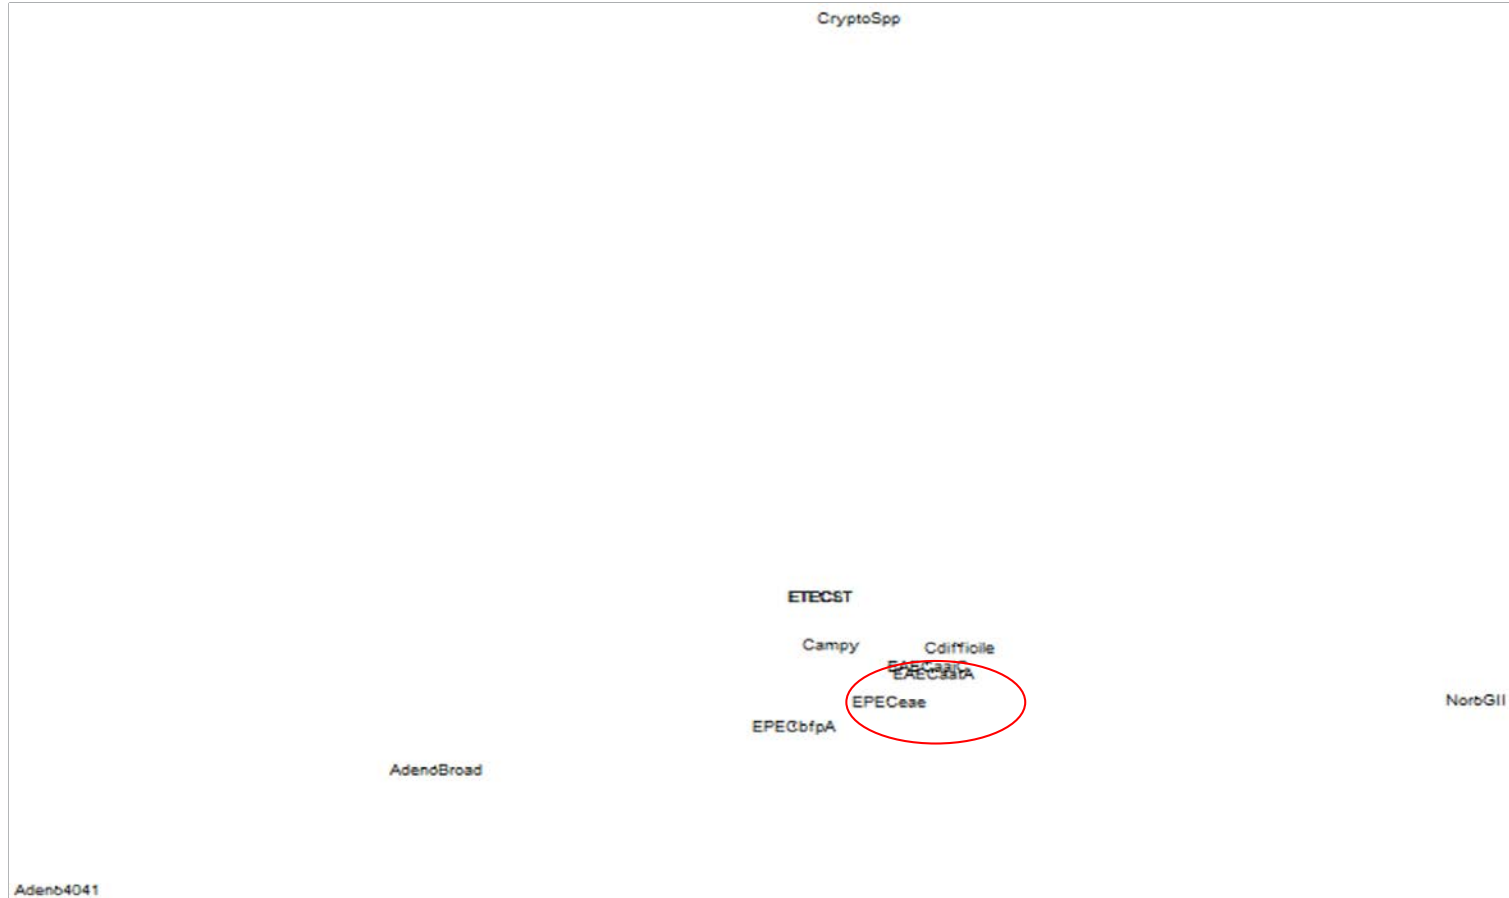

- Models introduced by Hoff et al. in 2002, and position estimation was done through a Markov chain Monte-Carlo algorithm.

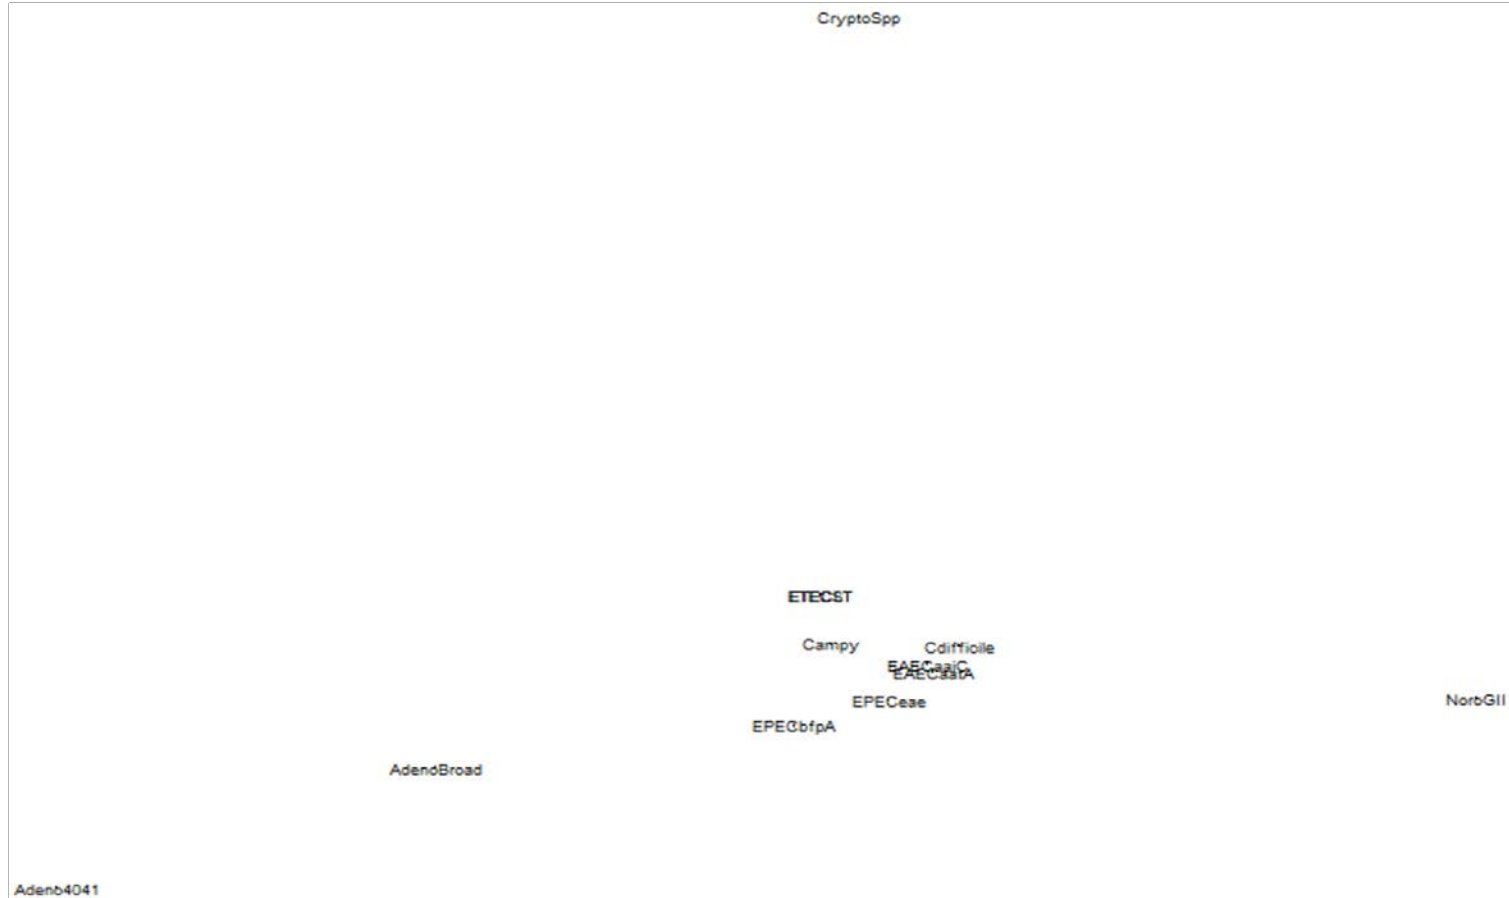

# Latent Position

# Latent Position

# Latent Position

---

# Can milk contamination predict colonization?

Analysis done using midline culture and self reported diarrhea data

# Logistic Regression

---

- Binary outcome: self-reported diarrhea
- Culture data on Ecoli, Shigella, EHEC, entero
- Used logistic regression
  - $P(\text{diarrhea}) = f(\text{Ecoli}, \text{Shigella}, \text{EHEC}, \text{entero})$

# Logistic Regression

Pathogens	Estimates	P-value
<i>(Intercepts)</i>	-1.595e+00	< 2e-16
Shigella	5.055e-06	0.309
Ecoli	-1.521e-03	0.739
EHEC	7.232e-07	0.719
entero	5.437e-07	0.899

- The presence of each pathogen has little to no effect on the odds of the individual having diarrhea.

# Conclusions

---

- **Prevalence:** Infants in low-income areas are colonized with many diverse pathogens which are known to cause enteric diseases.
  - Most prevalent: EAECaatA and EPECeae
  - Least Prevalent: Salmonella, Cholera and Giardia
- **PCA:** The pathogens we studied can be divided into 5 different clusters
- **Latent Space:** The latent space showed that there are strong indications of symbiotic relationships between certain pathogens that merit further exploration.
- **Logistic Regression:** Our data suggest that diarrhea is not an effective tool for identifying colonization of enteric pathogens in children.

# Acknowledgements

ISIB Program sponsored by the National Heart Lung and Blood Institute (NHLBI), grant # HL-147231.

Dr. Gideon Zamba, Amy Hahn, and the University of Iowa Biostatistics Department for their excellent work developing and facilitating this program.

Dr. Dan Sewell and Dr. Kelly Baker for their mentorship and permission for data use during this project.

---

**THANKS!**
