

Sleep Apnea and Bone Marrow Transplant Recovery

Finn Beruldsen, Brianna Lau
Patrick Breheny, PhD

1.

Context and Hypotheses

Context

- Sleep apnea (SA) - est 26% prevalence in 30-70 y/o
 - Negatively impacts the immune system
- Bone Marrow Transplant - common cancer treatment
- Mouse model suggests mimicking SA increases cancer susceptibility / progression

Questions

- Do the earlier results (from mice model) generalize to humans?
- Does SA or its risk factors worsen recovery?
- What metrics should we use to quantify immune system recovery?
- How do we work with censored and incomplete data?

Hypotheses

- SA + risk factors are related to:
 - longer hospital stay
 - slower immune recovery
 - decreased survival post-surgery
- Risk factors = obesity, diabetes, hypertension, age

2.

Data & Methods

Electronic medical record (EMR)

- Source: BMT records at Ulowa Hospital (2015-2021)
- 599 transplants on 510 unique patients
- Key feature of EMR data:
 - Not collected for research purposes
 - Diabetes, Sleep Apnea, Hypertension: ICD-10 codes
 - Obesity: Patient vitals

Cohort Demographics

Characteristic	N (%)
Deaths	153 (30%)
Hospital Deaths	19 (3%)
Gender (Male)	365 (61%)

Characteristic	Mean (Range)
Age	57 (18-79)
BMI	29 (16-50)

Number of Conditions

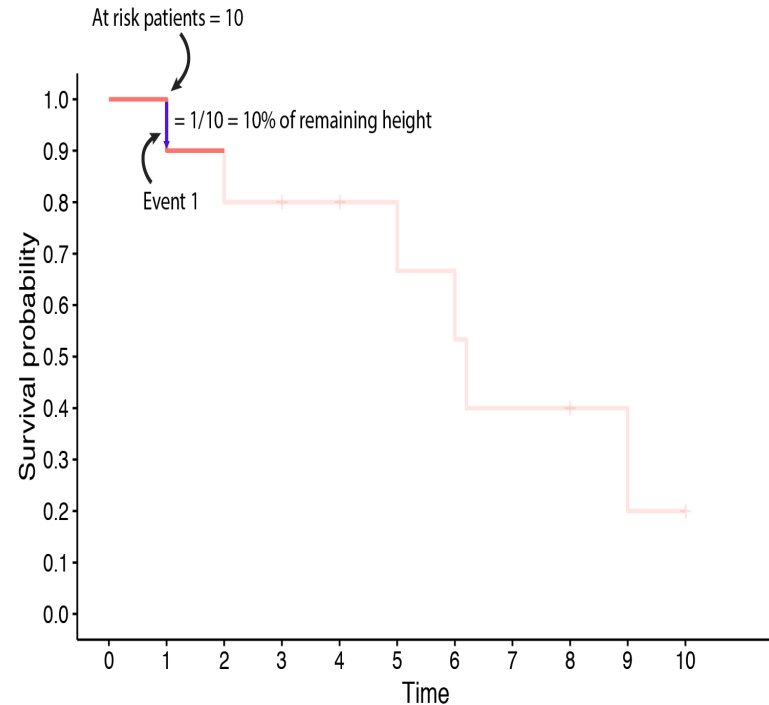

Conditions by Percent of Transplants

Time to Event Analysis

- Time to death (survival)
 - Handle partial information
 - Can estimate median time
- Time to hospital discharge
- Censoring = died in the hospital
 - T-test would be misleading (Dying is the fastest way out of a hospital)

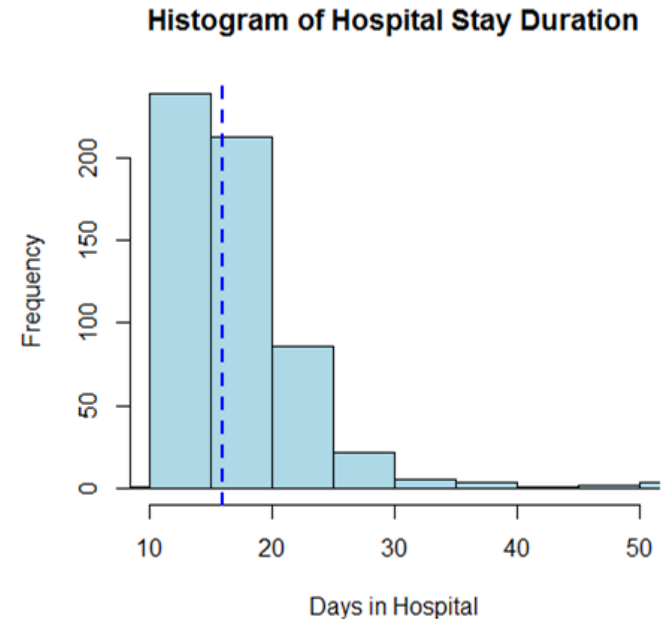

3.

Results

Distribution of Hospital Stay Duration

- “Long” hospital stay appears to be rare outcome
 - Range: 10 - 91 days
 - Overall median \approx 16 days
 - Hospital stay \geq 20 days: 158 (26%)
 - Hospital stay \geq 25 days: 56 (9%)
 - Hospital stay \geq 30 days: 26 (4%)

Sleep Apnea

Sleep Apnea vs. No SA Risk Factors

Obesity

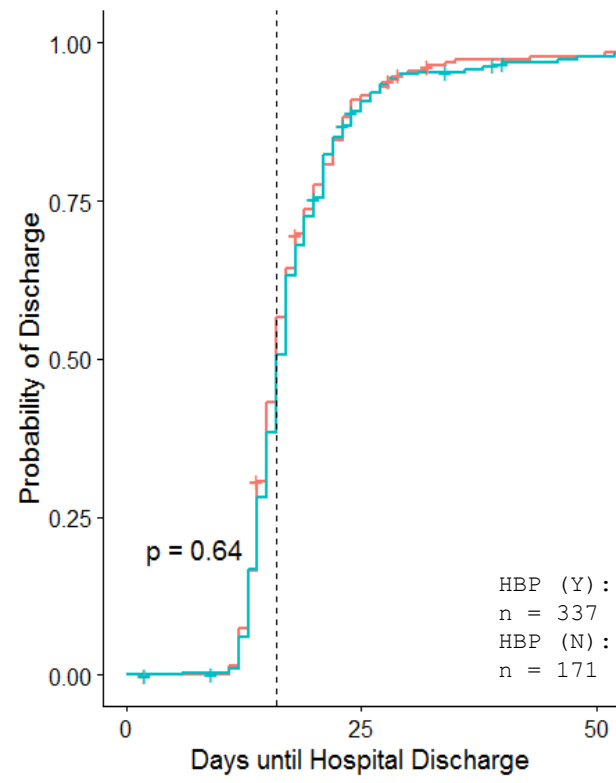

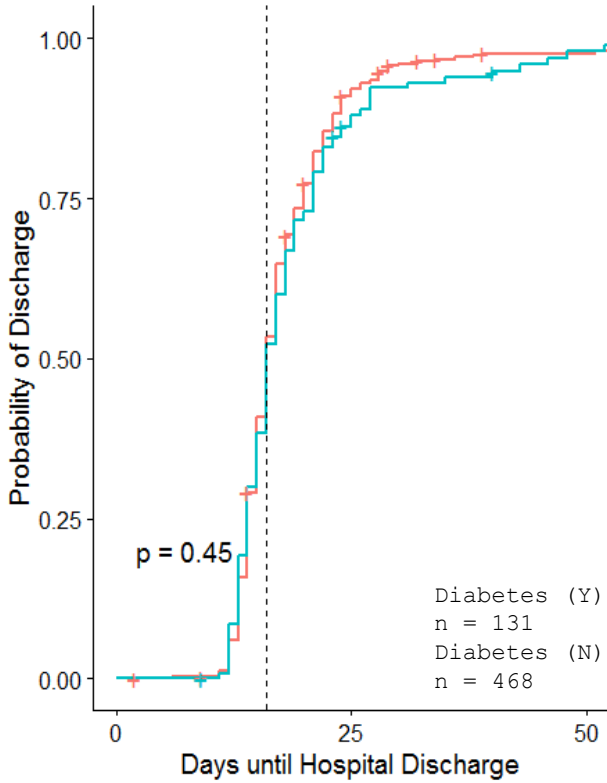

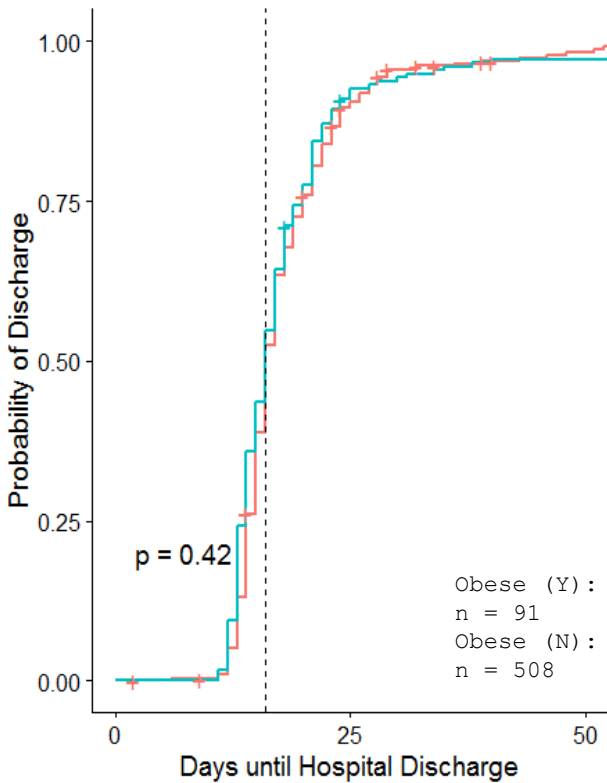

Diabetes

Hypertension

Number of Conditions

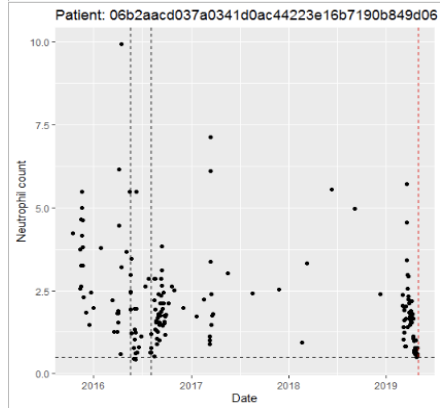

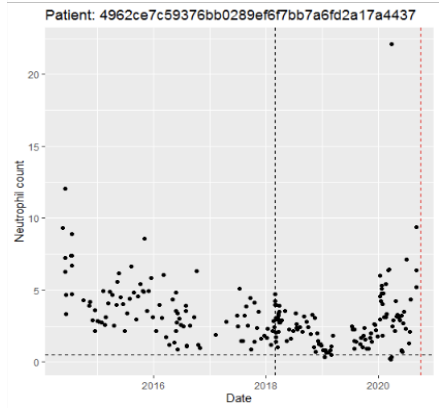

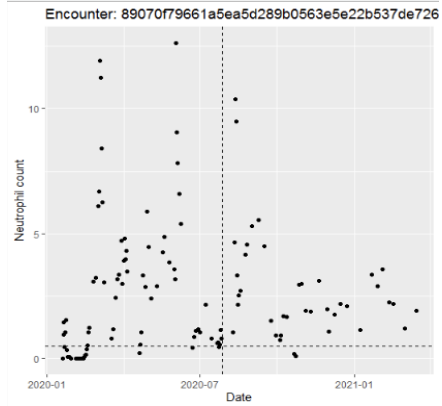

Sleep Apnea

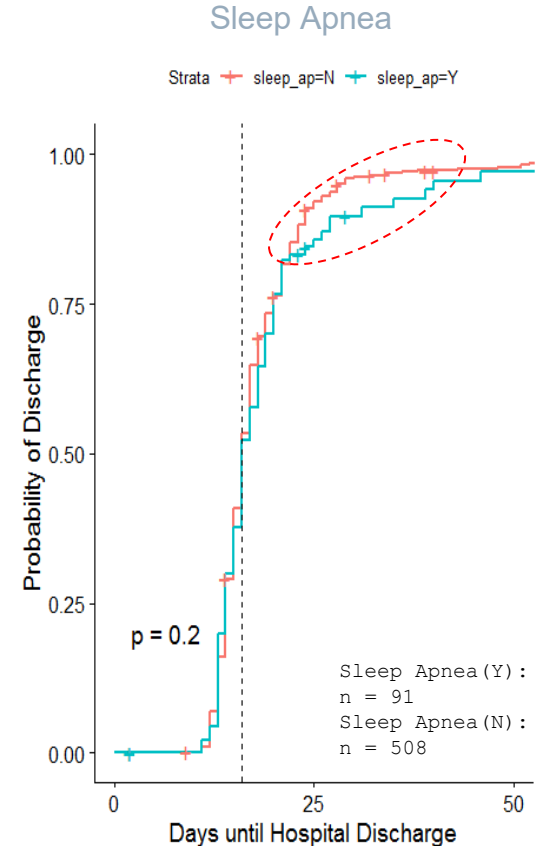

Neutrophil Counts

4. Conclusions

Conclusions

- No significant evidence of relationship between morbidities, hospital stay length, or low neut counts
- Suggestive association with sleep apnea
 - Sleep Apnea underdiagnosed
 - Lack power to detect rare outcomes
- Hospital stay- imperfect proxy for recovery
 - Hospitals aim to minimize inpatient stay
- Difficult to interpret number of low neutrophil count measurements

Implications for Clinical Assumptions

- Neut Count < 500 cells/mm³ is a somewhat extreme outcome
 - Pre/post transfusion neut counts coded together
- Similar median hospital stay regardless of condition or number of comorbidities
 - Potentially make transplant criteria more inclusive

Future research:

- Investigate commonalities in cases of hospital stay > 20 days
- Explore different outcome metrics

Supplemental Number of Conditions

Supplemental Race

Strata

- age_group=10-19
- age_group=20-29
- age_group=30-39
- age_group=40-49
- age_group=50-59
- age_group=60-69
- age_group=70-79

Supplemental Outcomes + Clinical Assumptions

- Hospital stays: well-documented in EMR
 - Proxy for time to immune system recovery
- Low neutrophil count concentration (< 500 cells/mm³) is a reliable indicator of poor immune system recovery.
 - <500 is severe and should not be discharged
- Comorbidities believed to inhibit immune system recovery post-transplant

Strata + young_old=10-49 + young_old=50-79

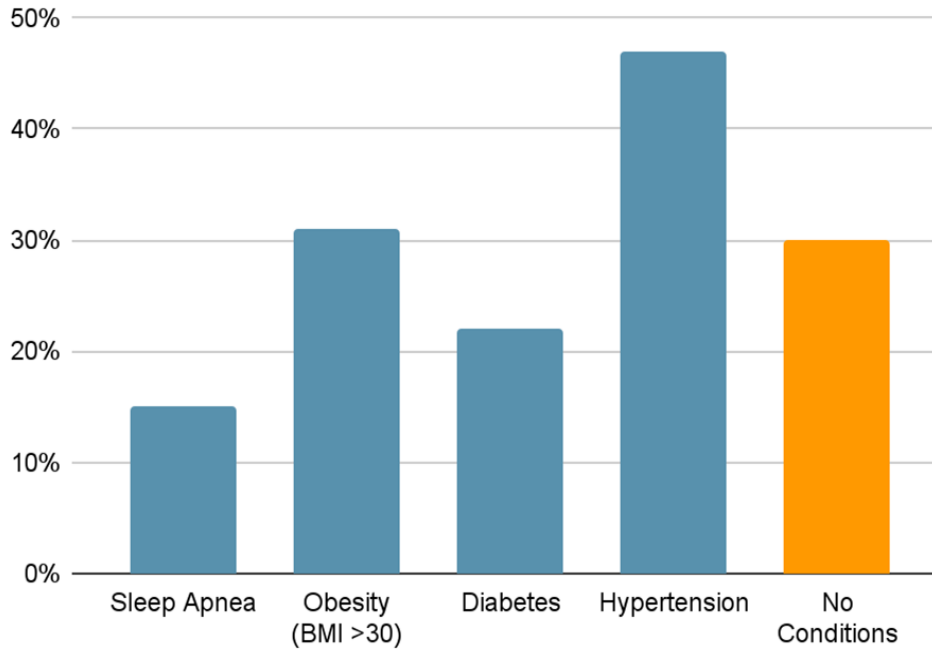

Summary

Condition	% of transplants
Sleep Apnea	15%
Obesity (BMI >30)	31%
Diabetes	22%
Hypertension	47%
No Conditions	30%
Total	n = 599

Number of Conditions	% of transplants
0	182
1	198
2	129
3	67
4	23
Total	n = 599

Summary: Risk Factors

Conditions by Percent of Transplants

Number of Conditions

Cohort + Distribution of Hospital Stay

Characteristic	N (%)
Participants	510
Transplants	599
Deaths	153
Hospital Deaths	19 (3%)
Gender (Male)	365 (61%)

Characteristic	Mean (Range)
Age	57 (18-79)
BMI	29 (16-50)
Year of transplant	2015-2021

- “Long” hospital stay appears to be rare outcome
